STATUS OF TIGERS IN INDIA

2014

INDIVIDUAL TIGERS PHOTO CAPTURED

BY SELF-TRIGGERED CAMERAS

Tigers are the soul of India's forests; they are closely associated with all that is wild and untamed about the subcontinent. They occur in a wide variety of forest types, from mangrove swamps of Sunderbans, semi-arid areas of Rajasthan, deciduous forests of Central India, rain forests of Western Ghats to Himalayan forests in the North and North East. The tiger's role as top predator is vital in maintaining the health of an ecosystem. For many of these forested ecosystems, the tiger is an “umbrella” species, i.e. efforts to conserve tigers also benefit a wide spectrum of biodiversity. The tiger has been a national symbol of India since time immemorial; it was depicted on the Pashupati seal of the Indus Valley Civilization and was even the insignia of the Cholas and Tipu sultan. The combination of grace, strength, agility and enormous power has earned the tiger its place of pride as the national animal of India. Few other animals are so deeply embedded in our cultural ethos and popular imagination as the tiger - for instance it is a symbol of power and courage and is the “Vahana” of Goddess Durga. Being an integral part of our life and culture, it enables us to garner resources and public support for conserving representative ecosystems.

Though the conservation status of the tiger continues to improve, it is not yet out of danger. Only a strong commitment for the continued survival of this magnificent symbol of our heritage will save the charismatic tiger. Continued support and timely actions by the government, scientific management approaches as well as interventions by a vigilant civil society are key to successful tiger conservation. The first step towards effective management and formulation of policy is to gain an understanding of where the tigers are and how many are there. To achieve this goal, the National Tiger conservation Authority in partnership with the Wildlife Institute of India initiated country wide monitoring of tigers, co-predators and prey in 2006 to be followed every four years. The current estimation cycle of 2014 is the third cycle, which has continued to document a recovering tiger population from 1411 in 2006 to 2226 in 2014, at an estimated annual increase of six percent.

To estimate tiger numbers self-triggered camera “traps” were set up in forested habitats. When a tiger crosses in front of the camera trap, it triggers the sensing mechanism and enables the camera to take a picture of the tiger. The biometric identifier for each tiger is the unique stripe pattern on the left and right sides of its flanks, an analog to this is the human fingerprint for individual identification. To be able to capture both the flanks of a tiger, required for individual identification, a pair of camera traps is deployed opposite each other at each location. Tiger occupies 92164 km^2 area in India. We invested an effort of 4,05,449 camera trap days covering 9735 locations at 63 sites, resulting in over 14,000 photographs from which 1540 individual tigers were identified. With such a large capture of tiger photographs, it is essential to automate tiger identification through stripe authentication to minimize human error. An identification software specifically designed for tigers, “Extract-Compare”, was used to store and maintain a biometric database of tiger identification. This would assist in identifying individual tigers across years and landscapes.

CAMERA TRAP PLACEMENT BY RESEARCH BIOLOGISTS

PHOTO CAPTURE OF TIGER BY CAMERA TRAP

At sites where it was not possible to undertake camera trapping due to very low tiger numbers or unfavourable law and order conditions, fecal samples of carnivores were collected to estimate minimum number of tigers through genetic analysis. Using the DNA extracted, the scats were initially screened for species and following the confirmation of the sample being of a tiger, these samples were screened with eleven microsatellite loci for individual identification. A genetic repository of these tigers is maintained at the institute.

The aforementioned picture and genetic database maintained at the Wildlife Institute of India is crucial in forensic analysis i.e. the photograph or the genetic material from the skin of a poached tiger, can be matched with the tigers in the database. On a match being found, the origin of the poached tiger skin is known, allowing us to infer the location and likely period of the crime. The subsequent statistical analysis based on ecological information generated through the photo-capture, genetic database is crucial in understanding vital demographic parameters such as, average rate of survival, fecundity, population growth rate, connectivity and movement patterns. This information provides essential data for the assessment of management effectiveness, conservation programs as well as to help in combating wildlife crime.
